COMP5331 Project Proposal Comment

Group No.: 7
Title: Implementation and Comparison of Six Pedestrian Trajectory Prediction Models
Type: Implementation

Comment (given by Raymond):

1. This is an implementation project (Group 7) titled “Implementation and Comparison of Six Pedestrian Trajectory Prediction Models.” The group plans to implement and comparatively evaluate six pedestrian trajectory prediction models on the standard ETH/UCY benchmark, under the course topic of Mining Spatial and Temporal Data.
2. Supply or complete the missing technical sections so that the proposal clearly lists the six concrete models that will be implemented, the exact data-processing pipeline for ETH/UCY (leave-one-out protocol, observation/prediction lengths, etc.), the evaluation metrics (ADE, FDE, and any additional measures), and a realistic implementation schedule. Once the model list is fixed, obtain the original papers and any official code repositories, and then begin by implementing a common data loader and evaluation harness before coding the individual models.
3. Pedestrian trajectory prediction papers often differ in subtle but important experimental details (coordinate normalisation, social pooling implementations, sampling procedures for stochastic models, and exact train/test splits). These differences can make fair comparison difficult. The group must therefore standardise the data pipeline and evaluation code and document every deviation from the original papers. Training multiple deep models on ETH/UCY is computationally non-trivial, so resource planning and early verification of reproducibility are essential.
4. All six trajectory-prediction models, the shared data-processing pipeline, and the evaluation harness must be implemented independently by the group members. Official or third-party code repositories may be consulted only to clarify algorithmic details or hyper-parameter settings. Any reused code fragments must be minimal, explicitly acknowledged, and clearly distinguished from the group’s own implementation. Substantial copying of public code without proper attribution constitutes plagiarism.
